

<Marine Organism Rearing Log>

9 AM, August 8, 2022

Weather: Sunny

Water temperature: 18.1°C

It's a clean-up day! A day after feeding, we vacuum fluff-like poo of the flounders on the bottom of the tank and it's easily collectible. On the other hand, its of the abalones is sticky and it sticks to the bottom, so we need to use a bar to scale it beforehand.

What makes the difference? Food? Or biology?
